Project 24554

Engineering Review of Proposed Modified Alternative D - Smithwick to Wall

I have reviewed Ray Gigear's June 28, 2001 letter to you and the attached documents and have the following comments.

- 1. The horizontal and vertical alignments prepared by DM&E for the Modified D alternative route between Smithwick and Wall via a bypass of Rapid City appear to meet the criteria of modifying the existing alignment to maximum 1.0 percent grades and compensated 1.0 degree curves. The new alignment between the existing track south of Rapid City and the existing track east of Rapid City also appears to meet the criteria.
- 2. The horizontal and vertical alignments prepared for the proposed Modified D Alternative appear to represent a good faith and credible effort to develop an alternative rail alignment through this area meeting the design criteria noted in Item No. 1.
- 3. The earthwork for the resulting alignment is very unbalanced with a very large amount of excavation on the section from Smithwick to Rapid City and mostly fill on the section from Rapid City to Wall.
- 4. The amount of excavation is about three times the amount of fill, which will require large areas for the disposal of excess fill as it is unlikely a local or regional need could be identified for such a large quantity of fill and it is generally uneconomical to transport fill material for more than a few miles.
- 5. The earthwork quantities developed as part of the horizontal and vertical alignment appear to represent a credible estimate of the cut and fill that would be associated with the proposed Modified D alignment. However, the amount of excavation is probably understated, as it does not include any benching for the deep excavations (in excess of 100 feet). Benching of sideslopes (essentially stair-stepping from the bottom of the cut to the top) would be necessary to provide stable sideslopes, reduce the potential for erosion, and provide for drainage of runoff draining into the cut. Excavation also is based on a typical, or standard, rail ditch cross section (similar to the figures presented in Chapter 1 of the Draft EIS and typically used to conduct preliminary engineering analysis), that for some sections, such as where creeks would have to be rerouted into the cut, would have to be larger. Practical considerations such as snow removal may also call for larger ditches. Also no cut or fill was included for existing road alignment changes required to maintain crossings with the revised track

Draft

- alignment. That is, roads crossing the proposed rail alignment may require reconstruction, including fill or excavation, to either bring them to the same elevation as the rail line at the crossing or create sufficient elevational difference to allow for construction of a grade separated crossing.
- 6. The new alignment section of track includes crossing state highway 44. The track elevation at the highway crossing is about 10 feet above grade so the existing highway profile would have to be modified and/or a grade crossing constructed.
- 7. The revised alignment would require replacement of existing bridges and other drainage structures. The bridge crossing the Cheyenne River between Mile Post 44 and Mile Post 45 would have to be about 40 feet taller than the existing structure. Likewise the bridge crossing the Cheyenne River near Mile Post 602 would have to be 50-60 feet taller. Crossing rivers and streams requires a bridge or culvert, with fill placed on either side of the crossing structure. Minimizing the actual bridge length (and subsequently the cost because bridging is more expensive per foot than filling) would require a large fill area footprint in the flood plain. Like the existing alignment, there would be many smaller structures required for streams crossing back and forth under the track which would have to be raised or lowered to account for the new gradeline.
- 8. At numerous locations the excavation for the revised alignment cuts off creeks that cross the track, resulting in the cut being lower than the creek and the creek flow draining into the cut. In some instances the creek flow only has to be conveyed a short distance in the track side ditch until the creek crosses back under the track and the flow can be returned to the creek channel. There are also several instances where the depth of cut requires quite long distances (several miles) of trackside ditch flow before the creek water can be discharged back to the existing surface/channel drainage. Most of these interruptions in channel flow only impact the hydrology of a narrow area along the track alignment but potentially much of this narrow area could be wetland. Additionally, these sections of stream would effectively be de-watered, impacting stream wetlands, water for livestock, and the ability to use stream water for irrigation.

Overall the modified Alternative D route is probably technically feasible but not reasonable or practical considering Alternative D provides no advantages such as reducing travel distance and other alternatives are available with significantly less impact and cost.

Pierre - Highway 14 Grade Separation

[THIS PAGE INTENTIONALLY LEFT BLANK]

Date: September 30, 2001

To: Steve Thornhill

From: Randy Sedlacek

Re. STB - DM&E

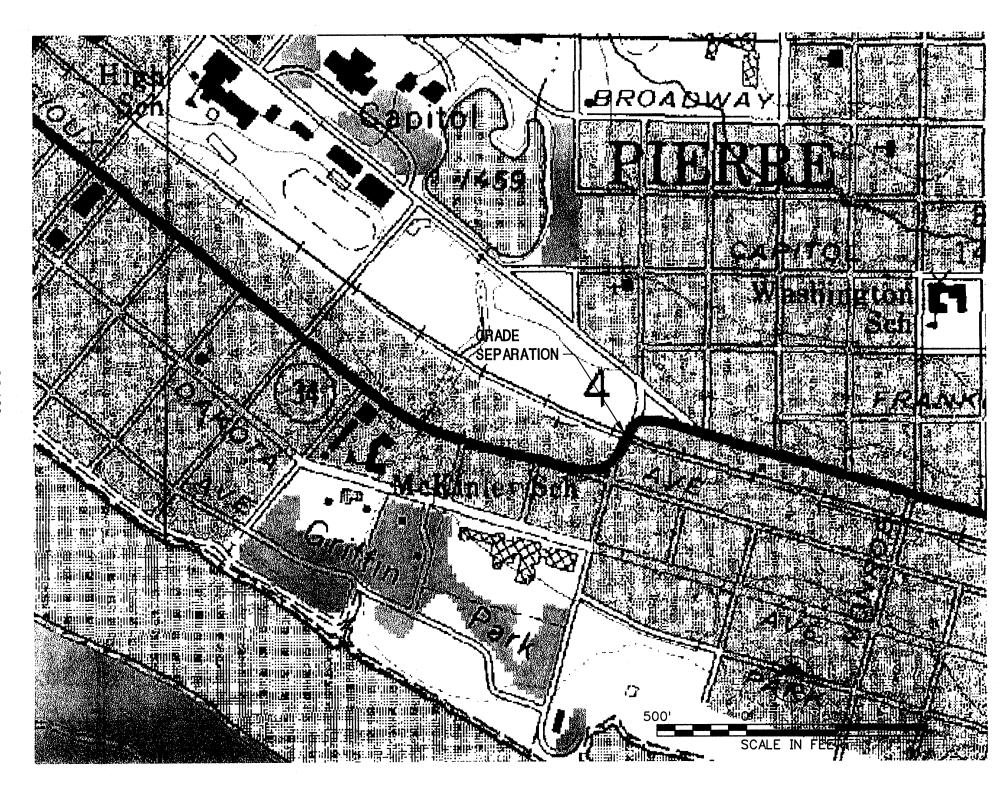

Project 24554

Pierre - Highway 14 Grade Separation

A grade separation at the Highway 14 crossing could be constructed using the existing horizontal alignment. The beginning of the approach on the west end of the bridge would be just east of Parkwood Street. The west approach would block access to Highway 14 from the short street between Parkwood and South Washington and from East Sioux. The east approach would bloc access from Wells Avenue, North Washington, and North Adam with the beginning of the east approach just west of North Jefferson. The overpass height and approach grades were taken from Chapter X, A Policy on Geometric Design of Highways and Streets, AASHTO.

Without some service streets adjacent to the overpass approaches several businesses on both the north and south sides of the tracks would be restricted or eliminated.

With the grade separation traffic between East Capitol and Highway 14 that now uses the intersection at Wells Avenue would have use North Jefferson. Traffic that now uses the East Sioux/South Washington intersection with Highway 14 would have to use the South Monroe intersection. The grade separation would eliminate an at grade access from the north side of the tracks to the hospital but would provide an unrestricted access using North Jefferson. Depending on where the emergency vehicle was coming from on the north side of the tracks this route could be about four blocks longer but would not have the possibility of being blocked by a train.

Rochester - Broadway Grade Separation Cost Estimate

[THIS PAGE INTENTIONALLY LEFT BLANK]

Date: September 30, 2001

To: Steve Thornhill

From: Randy Sedlacek

Re. STB - DM&E

Project 24554

Rochester – Broadway Grade Separation Cost Estimate

Roadway Overpass:

It has been assumed the Broadway overpass would provide separation for both the main line and the siding to the south of the main line. If the overpass only provided separation for the main line the south overpass approach would interfere with the siding. The siding could possibly be relocated but that option was not considered for this estimate.

The overpass height and approach grades were taken from Chapter X, A Policy on Geometric Design of Highways and Streets, AASHTO.

The preliminary estimated cost for the Broadway overpass is \$6,200,000. This cost does not include traffic control/detours for construction, utility relocation, access modifications required to existing businesses.

Roadway Underpass:

It has been assumed the Broadway underpass would provide separation for both the main line and the siding to the south of the main line. If the underpass only provided separation for the main line the south underpass approach would interfere with the siding. The siding could possibly be relocated but that option was not considered for this estimate. The cost for two railroad bridges over the roadway has been included.

The underpass height and approach grades were taken from Chapter X, A Policy on Geometric Design of Highways and Streets, AASHTO.

The preliminary estimated cost for the Broadway underpass is \$6,250,000. This cost does include temporary track to maintain main line traffic during construction but does not include any temporary track for the siding. This cost does not include traffic control/detours for construction, utility relocation, access modifications required to existing businesses.

The underpass would have a much greater impact on maintaining rail service during construction. It also has a large unknown in the dewatering and associated groundwater design costs. The estimate does include a very preliminary cost estimate for a stormwater pump station. The underpass presents a possible hazard during very intense short duration rainfall events.

Preliminary Cost Estimate

The Preliminary Cost Estimate should be neat, legible and dated since a copy of it is now included with the Bridge Memo. The quickest way to calculate the Preliminary Cost Estimate is to multiply the area of the bridge deck by an average cost. The average cost should be adjusted up for items such as high skews, long piles, etc. You must also then add the costs of Approach Slabs, Bridge Removals, Cofferdams, Temporary Shoring, etc.

The average costs vary. Usually they fall within these ranges.

Type of Bridge	Avg. Price/Sq. Ft. of Deck
Prestressed I-Girder	\$45 - \$65
Prestressed Bulb-Tee	\$55 - \$75
Plate Girder	\$65 - \$85
Temp. Bridge(state furn.)	\$40 - \$45
Temp. Bridge(cont. furn.)	\$65 - \$75
Major Lake Crossing	\$150 - \$175
Major River Crossing	\$175 - \$200

A more accurate way of calculating the Preliminary Cost Estimate is to actually calculate some approximate quantities for the bridge and then multiply them by the unit prices supplied by the average bid prices for the previous year. If you set up a spreadsheet to calculate these quantities, it only takes a couple of hours to come up with. To estimate the pounds of reinforcing steel in a structure. multiply the number of cubic yards of concrete in the structure by 115 (125 on boxes).

No matter which method you use to calculate the Preliminary Cost Estimate, increase it for the following items: (PDM Fig. 1-02.1) (do not compound the increases and use your judgement)

Item 9	<u>6 Increa</u>	<u>3,</u>
Staged Construction	10	
Horizontally Curved	5	
Seismic Performance Cat. B	10	
Seismic Performance Cat. C	25	
Seismic Performance Cat. D	40	
Tight Site/Limited Access	3	

Here are some guidelines for estimating the cost of the removal of existing bridges:

Type of Bridge Removal	Cost per Square Foot
Simple Structures Over Streams	\$5
Girder Structures Over Roads	\$ 7
Conc. Slab Structures Over Interstate	s \$25
(quick opening of lanes to traffic)	

The following pages contain prices to aid you in determining your Preliminary Cost Estimate.

	LISTING OF STANDARD BID ITEMS:		ESTIMATED
		UNITS	UNIT COST
	EXCAVATION		
206-10.00	CLASS 1 EXCAVATION	C.Y.	\$40
